Species Summaries for the Southern and Eastern Scalefish and Shark Fishery

For stock assessments completed in 2015 in preparation for the 2016-17 fishing season
**Introduction**

These species summaries provide information on quota species assessed by Southern and Eastern Scalefish and Shark Fishery (SESSF) Resource Assessment Groups (RAGs): Great Australian Bight RAG (GABRAG); SharkRAG; ShelfRAG; and SlopeRAG. These assessment summaries apply to stock assessments completed in 2015 in preparation for the 2016-17 fishing season.

The summaries contain basic information on stock status, TACs and catch trends, assessment details and RAG comments. The summaries are designed to be a quick reference, and should be read in conjunction with RAG minutes and the applicable species stock assessments. Annual updates are completed for species that have a new stock assessment, were considered by the RAGs or species that are under AFMA rebuilding strategies. The most recent full set of species summaries can be found on the AFMA website.

A glossary of commonly used terms is available at the end of the document.

### Assessment:

<table>
<thead>
<tr>
<th>Stock indicator trends</th>
<th>Model fits a decline in abundance, consistent with the fishdown of a developing fishery. Biomass is high relative to targets.</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAG comments</td>
<td>GABRAG has some concerns over the availability of bight redfish, as catches are much lower than the assessment would suggest</td>
</tr>
</tbody>
</table>

The previous base case stock assessment (Klaer 2012) gave a much higher RBC of 4407 t, and a long-term yield of 2143 t. These RBCs were much higher because, as a result of a lack of contrast in the available data, the model estimate of unfished female spawning stock biomass was approximately 26 000 t (in contrast to the 2015 model’s estimate of 5 451 t).

The outcome of the substantially reduced virgin biomass estimate, is a substantially lower RBC estimate, even though the stock depletion levels are still well above the 41 per cent MEY target.

### Key model technical assumptions/parameters

### Significant changes to data inputs

1. Repeat the assessment from 2011 using the new software version SS3.24u.
2. Use the older version of SS3 (SS3.24f) to test the effect of using new software.
3. Add catch and commercial CPUE to 2014/15.
5. Add length composition data from 2011/12 to 2014/15; a new step this year was to keep the port and on-board ISMP data separate. In addition, length composition data from all surveys were included and, again, new this year, the on-board length composition data obtained through crew sampling from 2010/2011 – 2014/2015 were also included.
8. Add the ageing error matrix.
9. Estimate $L_{max}$ (a growth curve parameter).
10. Again use the older version of SS3 (SS3.24f) to test the effect of using new software.
11. New to this assessment, add the age composition data from the FIS for the years 2008/2009, 2010/2011, and 2014/2015, in which it is available.
12. Use variance estimates around the recruitment deviates to set the last estimated recruitment to 2004/2005. Accept fitted recruitment deviation bias adjustment values.
13. The variance of the different length and age composition data and the CPUE data were balanced to generate the initial base case. The balancing procedure this year attempts to apply more emphasis to the CPUE time series. The model balancing also involved increasing the recruitment variation from 0.2 to 0.34 as further bias adjustments were required after adjusting the variance estimates on different data streams.

### Comments on data

Data in the 2015 is more informative than for previous assessments. This is the result of the heavier fishing pressure applied to the fishery in the mid-2000s, and the 10-15 year delay before recruitment effects are seen in the fishery (given bight redfish late age-at-maturity).

### Implications for companion species/TEPs/multi-species fisheries

GABRAG has noted concerns regarding the lower catches of bight redfish in recent years, with catches being taken as bycatch when targeting deepwater flathead.

(RBC and total catch are calendar year; TAC and Commonwealth catch are fishing season)
Blue eye trevalla (*Hyperoglyphe antarctica*)

### Stock status summary

#### Stock structure

The assessment assumes one blue eye trevalla stock across the entire SESSF. Given current knowledge, the Slope Resource Assessment Group (SlopeRAG) recommended blue eye trevalla be assessed as a single stock (incorporating the continental shelf, seamounts and the Cascade Plateau). However, this advice may be reconsidered once the results of external work becomes available.

The Australian stock is considered to be separate from the New Zealand stock(s).

#### Stock status against reference points and trend

Tier 4 species use CPUE targets as a proxy of biomass targets.

The Tier 4 target reference point is the level of CPUE assumed to produce a spawning biomass of 48 per cent of unfished levels. The limit reference point is 20 per cent of unfished levels.

SlopeRAG agreed to use a revised catch per hook metric in the Tier 4 analysis in place of the previously used catch per record/day. The RAG considered the updated analysis to be a better reflection of CPUE in the early part of the fishery. The updated analysis confirmed that the previous Tier 4 assessment was conservative in nature, and that blue-eye trevalla are likely to be less depleted than the 2014 assessment indicated.

<table>

</thead>
<tbody>
<tr>
<td><strong>Ref year</strong></td>
</tr>
<tr>
<td><strong>Target</strong></td>
</tr>
<tr>
<td><strong>Limit</strong></td>
</tr>
<tr>
<td><strong>Recent</strong></td>
</tr>
</tbody>
</table>

The RAG considered the effect of Orca depredation on blue eye trevalla catch rates, and noted that Orca depredation in the auto line fishery is assumed to have now reached equilibrium.
In an alternative Tier 4 analysis, loss of catch due Orca interactions was treated as a discard. The Tier 4 with Orca-influenced catch rates suggested that the stock is more productive than the base case analysis that used non-whale affected catch rates. The RAG recommended that Orca-influenced catch rates not be applied to the Tier 4 analysis used to set the RBC. The RAG noted that the RBC will be a conservative estimate because these data are omitted. However if depredation rates have declined exponentially that could explain the CPUE increase observed without any change in stock abundance.

</table>

**Probability of recommended biological catch (RBC) (or other levels of catch) causing a decline below limit reference under proposed management**

Species that follow a HS rule that has been MSE tested will have a “very unlikely” score in this section (i.e. P<10%).

Tier 4 assessments do not assess the probability of being below the reference point. However, the RAG considers the current assessment to be conservative.

The RBC is taken from the MSE-tested harvest control rules. If the standardised CPUE series is a reasonable index of relative abundance the RBC will have a very low probability of causing a decline below the limit reference point.

**Alternative Catch Scenarios:** N/A (Tier 4)
Based on additional work presented in 2014, SlopeRAG confirmed that the Tier 4 estimate from 2013 was very conservative in nature, and recommended that the current step-down be paused pending a 2015 stock assessment.

**Tier Level & Discounts**

<table>

</tr>
</thead>
<tbody>
<tr>
<td>Discount factor</td>
<td>0 per cent. The RAG recommended that the discount factor not be applied due to the conservative estimate of the RBC and protection afforded the stock by fishing closures</td>
</tr>
<tr>
<td>Is a multi-year TAC in place?</td>
<td>☐ Yes (in place this season) ☑ No</td>
</tr>
<tr>
<td>Is a multi-year TAC recommended? (please provide a clear indication on whether the multi-year recommendation is a RBC (e.g. based on Tier 1 model output) or TAC (e.g. a roll-over of catch))</td>
<td>☐ Yes (recommended for future seasons) ☑ No</td>
</tr>
</tbody>
</table>

The RAG did not support putting blue eye trevalla on more than a single year TAC because:

- the CPUE is less than 65 per cent of the target
- the CPUE has changed rapidly and the 2014 CPUE data point is the only one above the target in the last seven years
- developing a CPUE-based breakout rule for blue eye trevalla would require a CPUE standardization; this is in effect a Tier 4 assessment

### Stock indicator trends
- Total blue eye trevalla catches have been declining since 2009.
- The long term trend in CPUE is has been mostly below the target since 2001. There has been an increase in CPUE over the last two years.

### RAG comments
- In 2014 SlopeRAG reviewed additional work that looked at the early part of the blue eye trevalla CPUE series. The updated work applied a 'catch per hook' metric in place of the 'catch per day' metric used in previous Tier 4 blue eye trevalla stock assessments.
- In 2015 the RAG noted that:
  - catch per record CPUE is a blunt performance measure which ignores changes in fishing behavior
  - catch per hook CPUE is more sensitive to changes but getting total hook numbers can be difficult
  - the log (catch per hook) data are more normally distributed than the log (catch per record) data, indicating that catch per hook data are more representative of the true CPUE and abundance
  - catch per hook data are less prone to distortion due to behavioral changes than catch per record data
  - auto-line CPUE remains uncertain due to some confusion in the database
  - using catch per hook data decreases the CPUE during the reference period, and increases the recent CPUE, making the recent biomass proxy more similar to that occurring during the reference period
  - Orca depredation in the auto-line fishery is assumed to have now reached equilibrium, but appears to have had
negative effects on the CPUE from about the early 2000s

- whale depredations and closures, if they have had an effect on CPUE, will make current estimates excluding these parameters more conservative and under-estimate abundance.

In 2015 the RAG agreed to use the catch per hook metric, noting that this is a better reflection of CPUE in the early part of the fishery. The updated analysis resulted in a lower CPUE in the early part of the data series, confirming that the previous Tier 4 assessment was conservative in nature and that blue eye trevalla are less depleted than the assessment indicated.

Alan Williams, Paul Hamer, Kyne Krusic-Golub and Jonathon Cool presented a report on their work investigating blue-eye trevalla stock structure. The project is funded by AFMA and FRDC and is due to conclude next year.

</tbody>
</table>
| **Stock status against reference points and trend** | Tier 4 species use CPUE targets as a proxy of biomass targets.  
The Tier 4 target reference point is the level of CPUE assumed to produce a spawning biomass of 48 per cent of unfished levels.  
The limit reference point is the level of CPUE assumed to produce a spawning biomass of 20 per cent of unfished levels. |
| **CPUE** | **East** | **West** |
| Target | 2.0717 | 1.9249 |
| Limit | 0.8287 | 0.7699 |
| Recent | 0.1861 | 0.2681 |

2013 Stock status: Currently blue warehou is expected to be below the limit reference point and is subject to a rebuilding strategy. The last agreed Tier 1 assessment in 2005-06 found the eastern stock to be depleted below the limit reference point. In contrast, the western stock was thought to be above the limit reference point and close to the biomass maximum sustainable yield (*B*_40) level. However, the assessment predicted that the western stock will have dropped below the limit reference point by 2007 if the landed catches remained high and if recruitment was average.

Biomass trend: The standardised CPUE for both stocks...
continue to be low and declining in 2012, however, due to avoidance of blue warehou by operators the use of CPUE as an index of abundance is no longer considered reliable.

Catches have been small over the last few years and below the incidental TAC, as a consequence of low catches there are little data.

### Assessment

**Stock indicator trends**
The RAG noted again its’ concern that CPUE is not a good index of abundance while there is an incidental catch TAC in place and industry is actively avoiding the species. An alternative primary index of abundance needs to be developed as a high priority for use in future stock assessments.

<tbody>
<tr>
<td>Limit reference point is 20 per cent of unfished biomass.</td>
</tr>
<tr>
<td>Target reference point is 48 per cent of unfished biomass.</td>
</tr>
</tbody>
</table>

**Stock status:** The last updated assessment in 2010 (updated from 2008), assessed eastern gemfish to be at 16 per cent of its unfished biomass, and hence to be below the limit reference point.

The Eastern gemfish Stock Rebuilding Strategy has been updated and was released in early 2015. The current rebuilding strategy is located [here](#). Biomass trend: When last assessed, the stock was estimated to have started rebuilding.

</table>
| Breakout rules for multi-year TAC | Observed standardised CPUE falls outside of 95 per cent confidence interval of that predicted by the Tier 1 assessment  
| | Aggregated catch and discards exceed 100t. |
| Have breakout rules been triggered? | N/A |

### Assessment

| Stock indicator trends | Landed catches remain well below the incidental catch TAC and have been declining  
| | Aggregated landings and discards are less than the TAC and declining |

### RAG comments

The RAG reviewed the 2014/15 data and noted:

- that 2014 was the first year that landings and discards totalled less than the 100 t TAC
- generally over half the gemfish catch is discarded, mainly due to small size. The FIS data do not show these small cohorts however this is not unexpected due to the time of year the FIS is run and that the FIS was not designed to give good indications of gemfish abundance
- there is little sign of older fish in the age frequencies
- eastern gemfish range does not appear to be contracting.

There was no formal assessment of eastern gemfish during 2015. Projections from the most recent assessment, updated during 2010, indicate that with average recruitment the stock would recover within 13 years which is within the rebuilding timeframe specified in the HSP.

CSIRO explored the sensitivity of an eastern gemfish survey on stock assessment. Different possible values of a survey index of abundance show that as the index increases, the spawning biomass correspondingly increases as well.

The RAG identified some risks and benefits in running a survey. The RAG does not support a survey and agrees that funds would be better spent exploring inclusion of data from different fleets into the assessment and looking at different recruitment scenarios in the assessment. These options are less risky than a survey and may be more useful when investigating rebuilding timeframes.

The RAG pointed out the eastern gemfish stock may now be at a new equilibrium and the stock may not rebuild under current conditions meaning the Eastern Gemfish Rebuilding Strategy under the Harvest Strategy Policy may be redundant.
Noting that the last assessment was done in 2010 AFMA Management is of the view that it would be useful to have a new assessment.

The RAG agreed that continuing with the 100t incidental catch MYTAC was appropriate. The RAG agreed to review the indicators and targeting analysis each year to monitor mortality levels.

| Key model technical assumptions/parameters | N/A |
| Changes to model structure/assumptions | N/A |
| Significant changes to data inputs | N/A |
| Comments on data | N/A |
| Implications for companion species/TEPs/multi-species fisheries | Historically there were reports of a companion species relationship between mirror dory and eastern gemfish which is likely to have changed due to avoidance of fishing the areas and depths that these species inhabit during the eastern gemfish spawning season. |

### Tier 1 stock projection

#### Projected biomass (include confidence intervals)

![Graph showing biomass depletion]

Eastern gemfish base-case time-trajectories of spawning biomass depletion. Projections under 0t catch (green) and 100t catch (blue) (0.05 and 0.95 percentile). Note: total catches (including discards) are often in excess of the current 100t bycatch TAC, which means the above trajectories are optimistic (from Little and Rowling 2011).

</thead>
<tbody>
<tr>
<td>Tier 4 species use CPUE targets as a proxy for biomass targets.</td>
</tr>
</tbody>
</table>

SharkRAG reviewed the target reference point for elephantfish in 2014 and supported a maximum sustainable yield proxy target of 40 per cent of unfished levels. This was based on consideration that elephantfish is not targeted, is considered sustainable and is a secondary commercial species contributing less than 1 per cent to the fishery GVP.

The Tier 4 target reference point is the level of CPUE assumed to produce a spawning biomass of 40 per cent of unfished levels.

**Stock status:** In the 2015 Tier 4 assessment the recent average standardised CPUE-based proxy for biomass was above the target reference point.

</tr>
</tbody>
</table>
| **Is a multi-year TAC recommended?** (please provide a clear indication on whether the multi-year recommendation is a RBC (e.g. based on Tier 1 model)
| ☑ Yes (recommended for future seasons) | ☐ No |
| SharkRAG supported a multi-year TAC for three years. SharkRAG recommended a RBC of 306 t based on a Tier 4 stock assessment which used standardised gillnet CPUE. |
| Breakout rules for multi-year TAC | Breakout rules recommended were:  
| | • If total mortality (including discards, state catch, and recreational catch) exceeds the most recent RBC by more than 10 per cent  
| | • If total mortality (including discards, state catch and recreational catch) is lower than 50 per cent of the most recent RBC  
| | • If there is a greater than 25 per cent change in any of the most recent standardised gillnet CPUE values  
| Have breakout rules been triggered? | N/A |

**Assessment**

| Stock indicator trends | N/A |
| RAG comments | In 2015 SharkRAG accepted an updated Tier 4 assessment for elephantfish based on standardised gillnet CPUE. SharkRAG recommended including discards in the assessment. This involved using the last four years of discard rate data and estimating the discard rate for the previous years.  
SharkRAG recommended an RBC of 306 t and supported a multi-year TAC. |
| Key model technical assumptions/parameters | N/A |
| Changes to model structure/assumptions | In 2014 SharkRAG recommended using the MSY proxy target of 40 per cent of unfished spawning biomass for elephantfish. This recommendation was accepted by AFMA management and subsequent RBCs have been calculated using the MSY proxy.  
In 2015 the model was based on standardized gillnet CPUE including discards. Discard estimates pre 2011 are based on average of the real discard estimates from 2011-14 (0.6009).  
The 2015 analysis also includes changes to annual recreational catch from 29 t in 2002 interpolated to 45 t in 2008 and 45 t thereafter. |
| Significant changes to data inputs | Yes – model now includes updated discard and recreational catch data. |
| Comments on data | N/A |
| Implications for companion species/TEPs/multi-species fisheries | N/A |
**Tier 4 assessment**

**Total removals and catch rates**

![Graph showing total removals and catch rates](image)

**Elephantfish – gillnet.**

*Top:* total removals (black), target catch (fine blue line, C*).

*Bottom:* standardized CPUE (black), target CPUE (lower blue line) and limit reference CPUE (lower red line). Thick lines represent the reference period for catches (1997-2007; top panel, blue), CPUE (1997-2007; bottom panel, blue), and recent mean CPUE (last four years; bottom panel; green). The fine blue line below the target CPUE is the revised target based on a 40 per cent B0 proxy target for non-target species in a mixed fishery. In this case the discard catches have been included in the CPUE estimates, thereby increasing them markedly.

| Research allowance | N/A | ☐ Included in TAC | ☐ In addition to TAC |

<td>22.2 per cent</td>
</tr>
</tbody>
</table>
Based on the 2013 stock assessment, SharkRAG supported an RBC of 2010 t for the entire fishery. Noting larger hook catch reduces the RBC, the RBC of 2010 t is based on the scenario of 75 per cent hook catch in SA which reflects current and expected fishing activity.

However, the RAG noted caution as:

- the RBC from the 2013 assessment is above historical catches for the fishery
- Commonwealth catch has never been sustained above 1900 t and catches at this level have historically driven down catch rates.

It is important to maintain long term distribution of catches in the three areas of fishery in order to maintain catch rates. The concern is decreasing catch rates will mean higher levels of effort are required to land the TAC which is likely to increase the fishery's impact on incidental species and issues with localized depletion of gummy shark.

Therefore the RAG supported maintaining the status quo of a Commonwealth TAC of 1836 t for the duration of the three year MYTAC.

<tr>
<td></td>
<td>• catches fall below 1200 t</td>
</tr>
<tr>
<td></td>
<td>• length frequencies from the line catch change substantially from the model parameters;</td>
</tr>
<tr>
<td></td>
<td>a) more than 15% of gummy shark caught by the line sector are shorter than 76cm in total length; or</td>
</tr>
<tr>
<td></td>
<td>b) more than 20% of the line caught gummy shark are greater than 130cm total length.</td>
</tr>
</tbody>
</table>

Have breakout rules been triggered?

| Have breakout rules been triggered? | In 2015 SharkRAG reviewed the breakout rules for gummy shark and noted that none had been triggered. SharkRAG noted that the number of line caught gummy shark >130cm breakout rule is close to the trigger and agreed that this should be monitored. SharkRAG noted that more smaller and larger fish are caught on longlines than on gillnets. |

Assessment

</thead>
<tbody>
<tr>
<td>RAG comments</td>
<td>SharkRAG 2, 2013 noted that there are no sustainability concerns with the RBC set for the 2014/15 season.</td>
</tr>
<tr>
<td></td>
<td>The RAG noted that careful monitoring is required of catch rates in Bass Strait and any impacts on size composition of sharks due to increased longline catches.</td>
</tr>
<tr>
<td></td>
<td>In 2015 SharkRAG noted it had no concerns with continuing the MYTAC, and supported maintaining the MYTAC at 1836t.</td>
</tr>
<tr>
<td>Key model technical assumptions/parameters</td>
<td>Because of the close relationship between the number of shark pups and both the number and length of mature females, SharkRAG uses pup production as a proxy for spawning biomass.</td>
</tr>
<tr>
<td></td>
<td>The model relies on gillnet caught shark that are primarily from four age classes of sub adults. Trends in adult biomass are poorly informed by the data. The model results are highly sensitive to the assumption made regarding density dependence. Density dependence is the way that modeled</td>
</tr>
</tbody>
</table>
Stock compensates for a fish down in the stock. i.e. how the productivity of the stock responds to changing abundance. Density dependence affects the mortality rate of sharks aged 0-30 years, as a function of $1+\text{ biomass}$.

It is assumed that larger / older sharks are less available to capture than younger sharks (this is in addition to gear selectivity constraints). This is applied to gillnet and line gear. While there is evidence supporting this assumption for gillnets, there as yet no evidence for longline.

A non-linear relationship between CPUE and available biomass is implemented though the assumption that “gear competition” applies.

**Changes to model structure/assumptions**

There were no significant changes to the model used in 2013 compared to the last assessment in 2010.

The model no longer considers tag return data after 2005.

Forward projections now incorporate the assumption that the South Australian catch will be 75 per cent hook caught with the remainder of the fishery close to 100 per cent gillnet caught.

**Significant changes to data inputs**

The following data were added to the 2013 model:
- Reliable observer data are now available including length frequency data from Tasmania.
- CPUE data up to 2012 were included for Bass Strait and Tasmania.
- CPUE data from SA after 2009 were not included due influence of fishery closures.

**Comments on data**

Recent large closures in South Australia are thought to have reduced the nominal and standardized CPUE in that state causing a break in the index of abundance.

The RAG emphasizes the importance of collecting length frequency data for all longline caught gummy shark across the fishery.

**Implications for companion species/TEPs/multi-species fisheries**

The gillnet fishery interacts with Australian sea lions in waters off South Australia. Interactions are mitigated by using trigger limits that close spatial zones for 18 months if an interaction occurs. Similarly dolphin in interactions in waters adjacent to the Coorong region in South Australia are manged in this way. The Coorong region is currently closed to gillnet fishing to mitigate dolphin interactions.
To reduce targeting, gillnet operators are subject to a rule that constrains their catches of school shark to 20 per cent of their gummy shark catches.

The RAG recommended that the same 20 per cent rule be applied to all school shark caught by longline inside 183m.

Tier 1 stock projection

Projected biomass

Pup production in thousands of pups (top panel) and pup production relative to 1927 (bottom panel) for the three gummy shark regions and two scenarios.

</tr>
</tbody>
</table>
| **Breakout rules for multi-year TAC** | The RAG has previously determined that if a MYTAC is adopted the following breakout rules are appropriate, which if triggered, the RAG would review the data and consider appropriate options that may include a new assessment:  
- observed standardized CPUE falls outside the 95 per cent confidence intervals  
- catch exceeds the individual east and west RBCs. | |
| **Have breakout rules been triggered?** | N/A | |

**Assessment**

| **Stock indicator trends** | **East** Stock status 2016: 36.5 per cent of 1988 spawning biomass. Trend: The decline in stock status has slowed and stock status is now relatively flat. Zone 10 and 20 standardized CPUE continues to decline, Zone 30 CPUE is flat.  
**West** Stock status 2016: 69 per cent of the unfished biomass Trend: The trend in stock status is increasing. Zone 40 and 50 standardized CPUE has been declining since 2001 and this trend continues. | |
| **RAG comments** | Both stocks are suitable for a three year MYTAC  
It should be noted that the assessment for the western stock is increasingly uncertain because;  
- only sporadic age data are available  
- length compositions are based on very low numbers of sampled fish  
- the catch in the western region is now very low. Bearing in mind that the eastern zone biomass is below target and that jackass morwong is managed under a single global quota, the RAG cautioned that there may be some risk to the sustainability of the eastern stock if a large amount of the ‘western’ quota is caught in the eastern zone. | |

<tr>
<th>Stock indicator trends</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAG comments</td>
<td>An alternative Tier 4 analysis for the eastern mirror dory was performed to determine the impact of the recent increase in the discard rate on the catch rates. In this case there was a marked effect, especially in three of the last four years, which are used in the estimate of current CPUE. The effect of this is to increase the estimate of the eastern RBC. This enables a reduction to the RBC due to the increased discard levels to be accounted for in the calculation of the TAC. Discards are not included in the western catch rates, consequently discards do not need to be accounted for in TAC calculations. Consistent with the 2014 RAG advice the RAG did not recommend a MYTAC given the apparently cyclical nature of mirror dory stock status and catches, and concerns that a MYTAC will not be able to respond to relatively rapid changes in biomass.</td>

</tr>
<tr>
<td>Based on the existing data and fishery dynamics multiple regional stocks of orange roughy are assumed and the fishery is managed and assessed as a number of discrete regional stocks. Recent genetic studies indicate little genetic diversity between all south east Australian stocks, however they may be demographically separate. The part of the southern zone catch that is caught on the Pedra Branca grounds is assumed to be part of the eastern stock and was assessed as part of the eastern zone 2014 base case assessment.</td>
</tr>
</tbody>
</table>

| **Stock status against reference points and trend** |
| The most recent accepted assessment (2000) concluded that the southern stock was less than the limit reference point. |

- **Limit reference point** is 20 per cent of unfished biomass.
- **Target reference point** is 48 per cent of unfished biomass.

Stock status: unresolved in the southern zone but considering that there has been minimal fishing in the southern zone and the eastern stock has rebuilt to a harvestable level it is not inconsistent to think that similar rebuilding may have occurred in the southern zone.

Orange roughy southern is managed under the Orange Roughy Rebuilding Strategy 2015.

The component of the southern zone stock that is caught in the Pedra Branca seamounts area is assessed as a part of the eastern zone stock assessment due to stock structure assumptions. The eastern zone assessment in 2014 estimated the stock status in the Pedra Branca area to be 26 per cent of unfished biomass.

Biomass trend: The 2004 and 2006 updates of abundance indices and observations of possible spawning aggregations (from acoustic surveys) indicated that rebuilding may be
The 2014 assessment of the eastern orange roughy stock also indicates that rebuilding is occurring in that area. Catches are extremely low therefore overfishing is unlikely to be occurring. The current TAC poses no risk to stock recovery.

Assessment

Stock indicator trends
Due to the incidental catch TACs with no targeted fishing, CPUE is not a reliable index of abundance.

The 2014 eastern orange roughy assessment (which includes stock residing in the Pedra Branca area of the southern quota zone), indicates that the stock referenced by the assessment has rebuilt to 26 per cent of unfished biomass.

RAG comments
The RAG has previously agreed that, despite the absence of an agreed assessment model, the data show there is little targeting or bycatch of orange roughy. As such the incidental catch TAC is applicable for the southern zone (apart from the Pedra Branca area) and does not impede recovery of the stock.

Bearing in mind the rebuild of the eastern stock from a low biomass, it could be argued that the southern and western zones should have recovered somewhat. This is tempered by not knowing if recruitment processes and stock movement in the southern and western zones are similar or different to those in the eastern zone.

It was pointed out that the eastern stock part of the southern stock had rebuilt to a certain degree and that the recovery will have to be watched for at least a decade to monitor if previous high catches have any effect on recruitment.

The RAG noted that the southern zone continues to be on rebuilding incidental TAC and the RAG found there was no additional information that would provide a basis for the RAG to change its’ previous TAC advice. The RAG recommended that the southern zone orange roughy MYTAC remains unchanged.

The RAG supported undertaking an externally reviewed desktop study of how evidence of rebuilding should be collected, is there currently any evidence/likelihood of rebuilding and identification of information gaps that preclude a stock assessment of the southern and western orange roughy stocks.

| RAG comments           | The RAG has previously agreed that, despite the absence of an agreed assessment model, the data show there is little targeting or bycatch of Orange Roughy. As such the incidental catch TAC is applicable and does not impede recovery of the stock.  
Bearing in mind the rebuild of the eastern stock from a low biomass it could be argued that the southern and western zones should have recovered somewhat. This is tempered by not knowing if recruitment processes and stock movement in the southern and western zones are similar or different to those in the eastern zone.  
It was pointed out that the eastern stock part of the southern stock had rebuilt to a certain degree and that the recovery will have to be watched for at least a decade to monitor if previous high catches have any effect on recruitment.  
The RAG noted that the western zone continues to be on rebuilding incidental TAC and the RAG found there was no additional information that would provide a basis for the RAG to change its’ previous TAC advice. The RAG recommended that the western zone orange roughy MYTAC remains unchanged.  
The RAG supported undertaking an externally reviewed desktop study of how evidence of rebuilding should be collected, is there currently any evidence/likelihood of rebuilding and identification of information gaps that preclude a stock assessment of the southern and western orange roughy stocks. |

<tr>
<td>Based on the existing data and fishery dynamics, multiple regional stocks of orange roughy are assumed and the fishery is managed and assessed as a number of discrete regional stocks. Recent genetic studies indicate little genetic diversity between all SE Australian stocks. However, they may be demographically separate. For assessment purposes the eastern stock is assumed to also include catches taken from both the eastern zone and the Pedra Branca area in the southern zone.</td>
</tr>
</tbody>
</table>

| **Stock status against reference points and trend** |
| Limit reference point is 20 per cent of unfished biomass. Target reference point is 48 per cent of unfished biomass. |

Stock status: The most recent assessment (2014) indicates that the stock is above the limit reference point, and is estimated to be at 26 per cent of unfished biomass for the beginning of 2015.

Orange roughy eastern is managed under the Orange Roughy Rebuilding Strategy 2014.

Biomass trend. Catches have previous to this year were extremely low and this population has increased to a biomass status of about 26 per cent of unfished biomass. The continued TAC poses no impediment to continued stock recovery.

| **ABARES most recent assessment (2015)** |
| **Biomass:** Uncertain | **Fishing mortality:** Not subject to overfishing |

| **GVP figures (2012-13 fishing season)** |
| **GVP** | **% fishery GVP** |
| $0.7 million | 1.2 per cent |
The RAG recommended a 3-year MYRBC based on the modelled projection of stock recovery:
Year 1 RBC – 381 t
Year 2 RBC – 512 t
Year 3 RBC – 647 t.
Subsequently, noting the longevity of this species AFMA set a 3 year TAC of 500 t per year. NB. as the stock occurs across both the eastern and southern zones the TAC is apportioned across both zones.

| Is a multi-year TAC in place? | ☒ Yes (in place this season) | ☐ No |

| Is a multi-year TAC recommended? (please provide a clear indication on whether the multi-year recommendation is a RBC (e.g. based on Tier 1 model output) or TAC (e.g. a roll-over of catch)) | ☒ Yes (recommended for future seasons) Based on Tier 1 modelled stock projections | ☐ No |

| Breakout rules for multi-year TAC | Given the long-lived nature of orange roughy and an expectation that there would not be large year-to-year changes to age structure that reflect stock size, and that CPUE was not considered an adequate indicator of stock status for aggregating stocks, the RAG could not identify breakout rules for eastern Orange Roughy. It also, however, did not see a strong need for such rules. |

| Constant catch scenarios | As part of the 2014 assessment AFMA requested CSIRO to undertake model runs for three constant future catch scenarios (400t, 450t and 513t).  
- Estimates of female spawning biomass were the same for using the HCR and the constant catch of 513 t. |
Have breakout rules been triggered? N/A

Assessment

Stock indicator trends

Due to incidental catch TAC with no targeted fishing, CPUE is not a reliable index of abundance.

RAG comments

The Tier 1 model inputs include: re-aged otolith data, updated age error matrix, catches from eastern zone and Pedra Branca in the southern zone, male and female age composition and abundance indices from acoustic sampling.

The outcome of the assessment is sensitive to stock structure assumptions and across different stock structures gave depletion estimates. Given the model sensitivities to stock structure, further exploration of stock structure should be undertaken in future. The stock structure assumption used in the 2014 base case (East plus Pedra Branca) gave the best fits to data.

The RAG noted that because the catch series used in the assessment comes from both the eastern and southern zones the assessment does not fit in with current management.
Given that it appears that orange roughy in the eastern zone (which was historically heavily fished) is above the limit reference point, the RAG asked whether the southern and western zones may also have recovered to a similar extent. However there have been no surveys in these areas and hence, without evidence, it is difficult to ascertain if any recovery is occurring.

SlopeRAG, at its 2015 meeting, supported an acoustic optical survey (AOS) of the St Helen’s Hill and St Patrick’s Head areas in 2016. The main survey objectives are: obtaining an estimate of spawning orange roughy to add to the existing time series, collection of biological samples to add to the biological indicator series and collect orange roughy for reproductive potential assessment.

The RAG recommended that the current 500 t eastern zone MYTAC remain noting that current orange roughy catches are within the TAC and there was no reason to depart from previous advice.

The RAG recommended granting 110 t of eastern zone orange roughy research catch allowance (RCA) in season 2016-17 for the eastern zone AOS. The RAG recommended that the RCA is within the 500 t TAC.

<td>Assessed using CASAL based stock assessment model. See Cordue (2015) for technical assumptions and parameters.</td>
</tr>
</tbody>
</table>
| **Changes to model structure/assumptions** | The 2015 pink ling assessment started as an update of ISL’s 2013 assessments however this was expanded to include further analysis of eastern selectivity and estimates of natural mortality (M) following MCMC runs. New data were added on to existing models and (as far as possible) the same methods were applied. A full Bayesian estimation was undertaken (MPD runs for diagnostics followed by MCMC runs for estimates). MCMC convergence proved problematic:  
  - West: one chain diverged substantially from the other two, giving very different stock status estimates. Reasons for this needed to be determined |
East: one chain differed from the other five and looked anomalous and needed further investigation.

East- Two selectivities were estimated for the non-trawl fishery for port and at-sea sampling but they were very similar. The three trawl selectivities were all allowed to be domed. In the early period (before 2000), the selectivity was fairly flat, in the second period it was very domed, and in the most recent period it was moderately domed. This result differs from the MCMC assessment in 2013 where all three selectivities were domed (Cordue 2013).

The RAG did not accept the the first eastern base case noting:

- that flat topped trawl selectivity prior to 2000 is unlikely and inconsistent with domed shaped selectivity over the two later periods
- the optimistic estimate of natural mortality, median 0.26.

A further eastern MCMC model was run to produce a base model with more acceptable diagnostics. Only minor changes were made and the run was confirmed as the accepted base case model.

### Significant changes to data inputs

Given the recent and changeable trip limits in the eastern ling fishery updating catch histories and CPUE was relatively complicated. The stock assessment models require data on catch (landings plus discards) rather than just landings. Trip limits could have been expected to cause some level of additional discarding in the eastern fisheries. The scale of the discards were estimated and used to prepare the eastern catch history and to give context to the eastern CPUE indices.

Trip limits formed part of the management arrangements to constrain catches in the eastern zone and although trip limits will reduce landings is not so obvious whether they will reduce total fishing mortality (removals).

In the eastern standardized CPUE analysis, period effects were estimated for when there was no trip limit, a 50 kg per day trip limit, and a 250 kg per day trip limit. The period effects include changes in behavior and the level of discarding:

- analysis of ISMP data for the same time periods produced “landings multipliers” (what the landings need to be multiplied by to get the removals)
- the period effects and landings multipliers can be combined to compare total removals under the two trip limit levels against the expected removals when no trip...
limit (for the same level of effort): 50 kg per day

- removals ≈ 0.83 × removals when no limit (i.e. a 17% reduction in the catch) 250 kg per day
- removals ≈ 0.88 × removals when no limit (i.e. a 12% reduction in the catch).

The methods used by ISL in the 2013 assessment were applied (Cordue 2013). However, in some eastern runs, “period effects” were estimated to account for the discard and avoidance behaviour in 2013 and 2014 in response to trip limits. The eastern and western trawl fisheries were modelled separately. When the eastern “period effects” were not estimated, the form of the models was the same for both east and west:

**Recommended Biological Catch 2016-17**

Given there are no new data available that would inform a change of decision the RAG recommended continuing with a RBC of zero and an incidental catch TAC of 100 t.

The 100 t bycatch TAC was recommended based on the analysis that indicated catches up to 150 t would allow rebuilding in a similar timeframe to lower catches, and making allowances of 50 t for state catches and discards. This also factors in the potential for strong recruitment to enter the fishery in the next few years, and the need to avoid unnecessary discards if possible.

**Overcatch/undercatch**

<table>
<thead>
<tr>
<th>Probability of recommended biological catch (RBC) (or other levels of catch) causing a decline below limit reference under proposed management Species that follow a HS rule that has been MSE tested will have a “very unlikely” score in this section (i.e. P&lt;10 %).</th>
<th>NIL</th>
<th>N/A – the stock is assessed as being below the limit reference point</th>
</tr>
</thead>
</table>

**Alternative Catch Scenarios:** catches from between 0 t and 150 t provide for rebuilding to the limit reference point by 2019 (assuming average recruitment).

</tr>
<tr>
<td><strong>Implications for companion species/TEPs/multi-species fisheries</strong></td>
<td></td>
</tr>
<tr>
<td>Companion species analysis indicates that the majority (64 per cent) of all redfish are taken in shots where redfish is not the most valuable component of the catch. This suggests it is not normally targeted.</td>
<td></td>
</tr>
<tr>
<td>Flathead is the species most commonly being targeted when redfish are caught (31 per cent).</td>
<td></td>
</tr>
</tbody>
</table>
The last companion species analysis (Klaer, 2010) indicated that of 156 t of redfish caught, 100 t was caught in shots where redfish was not main species taken.

In the 2013/14 fishing season, 90 t of redfish was landed while 2309 t of flathead was landed, suggesting that full quota utilisation of flathead does not result in substantial redfish mortality (total redfish discards in 2013 was 29 t).

Projections completed in the 2014 redfish stock assessment showed that redfish would rebuild by 2018 or 2019 at catches of 0 t, 50 t, 100 t and 150 t (i.e. catches up to 150 t made little different to the projected rebuilding rate for redfish).

Catch trends – Redfish
(RBC and total catch are calendar year; TAC and Commonwealth catch are fishing season)
Sawshark (*Pristiophorus* spp.)

**Stock status summary**

**Stock structure**

Three endemic species of sawsharks occur off southern Australia, but their distributions have not been described precisely. Common sawshark (*Pristiophorus cirratus*) is reported to range from Jurien Bay in WA to Eden in NSW, including Tasmania, to depths of 310m. Southern sawshark (*P. nudipinnis*) is reported to range from the western region of the Great Australian Bight to eastern Gippsland in Victoria, including Tasmania, to depths of 70m. The eastern sawshark (*Pristiophorus* sp. A) is reported to range from approximately Lakes Entrance in Victoria to Coffs Harbour in NSW at depths of 100–630m (Last and Stevens 1994).

Little is known of stock structure or movement rates.

For assessment purposes, all sawsharks south of the Victoria–NSW border are assumed to be common sawshark and southern sawshark, whereas those north of this border are assumed to be eastern sawshark.

**Stock status against reference points and trend**

SharkRAG reviewed the target reference point for sawshark and supported an MSY proxy target of B40. This was based on consideration that sawshark is a secondary commercial species and not targeted, is considered sustainable and contributes about 1 per cent to the fishery GVP.

This Tier 4 target reference point is the level of CPUE assumed to produce a spawning biomass of 40 per cent of unfished levels. The limit reference point is 20 per cent of unfished levels.

</tr>
</thead>
<tbody>
<tr>
<td><strong>Stock structure</strong></td>
<td>The assessment model assumes that there is one well mixed stock. Tagging and genetic data shows some evidence for one well mixed stock. However, earlier data suggests there could be an east/west divide in stocks. This is supported by research documenting a collapse in the eastern part of the fishery around Tasmania and Bass Strait. After this collapse a fishery subsequently established in the west suggesting a reproductively isolated stock.</td>
</tr>
<tr>
<td><strong>Stock status against reference points and trend</strong></td>
<td>Target reference point is 48 per cent of the unfished biomass (pup production is used as a proxy for breeding biomass). Limit reference point is 20 per cent of the unfished biomass (pup production is used as a proxy for breeding biomass). In 2014 SharkRAG noted for the first time that there is quantitative evidence from the trawl CPUE series that school shark is slowly rebuilding. There has been a sustained increase in trawl CPUE since 2003. Bottom longline CPUE data are available from 2012-14 and catch rates from this method also appear to be increasing over time. In 2015 SharkRAG noted there is an overall increasing trend in trawl CPUE and increased pupping in a historically important pupping area (Pittwater, Tasmania). This is consistent with anecdotal evidence and catch reports from industry that school shark abundance is increasing. The stock is currently assessed at below the limit reference point. However the RAG considers that the weight of evidence supports that the stock is rebuilding and not subject to overfishing within the rebuilding time of three generation times.</td>

<tr>
<th>Stock indicator trends</th>
<th>Gillnet CPUE is not considered a reliable index of abundance as school shark are actively avoided by gillnet fishers.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>In 2015 SharkRAG noted that there are continuing positive signs suggesting that the school shark is rebuilding. This is based on an overall increasing trend in trawl CPUE (since 2003) and increased pupping in an historically important pupping area. This is consistent with catch reports from industry that school shark</td>
</tr>
</tbody>
</table>
abundance is increasing.

Figure below. School shark trawl CPUE.

Bottom longline CPUE data is available from 2012-15 and catch rates are increasing over this time.

A close kin genetics project is in progress to develop alternative and independent measures of abundance for the stock. An absolute estimate of abundance is expected by the end of 2017.

**RAG comments**

Assessments (since 1991) have consistently estimated the school shark population to be below the limit reference point of 20 per cent of unfished levels.

SharkRAG recommended school shark catches in 2016/17 be restricted to a level that covers unavoidable bycatch and discards only. SharkRAG considers 215 t to be the best estimate of unavoidable bycatch including discards. This is based on landed catch from 2011 and ISMP estimates of discards of 9 per cent.

SharkRAG noted that there are continuing positive signs suggesting that the school shark is rebuilding. This is based on an overall increasing trend in trawl CPUE and increased pupping in a historically important pupping area. This is consistent with anecdotal evidence and catch reports from industry that school shark abundance is increasing.

SharkRAG expressed concern over the potentially high catch of school shark by state fisheries and would like reliable measures of total catch along with information on size frequency.

SharkRAG strongly recommended that species specific catches are reported and efforts should be implemented to ensure the state catch of school shark is minimised.

SharkRAG noted there were concerns about the total mortality given increasing discards. The RAG supports getting better information on the survivability of released sharks.
| Key model technical assumptions/parameters | The assessment model assumes that there is one well mixed stock. |
| Changes to model structure/assumptions | The stocks intrinsic rate of productivity, held fixed at 3.5 per cent since the 2006 stock assessment update, was estimated by the model during 2012, using (but not updating) the 2009 stock assessment model. The new runs of the model showed that a productivity value of 4.4 per cent is more consistent with the available data. |
| Significant changes to data inputs | N/A |
| Comments on data | There are concerns in relation to gillnet CPUE data used in the model due to operators avoiding school shark. As a result, concern remains about the ability of the school shark assessment to reliably estimate the state of the stock. A close kin project is underway and is expected to provide an absolute measure of abundance. |
| Implications for companion species/TEPs/multi-species fisheries | The gillnet fishery interacts with Australian sea lions in waters off South Australia. Interactions are mitigated by using trigger limits that close spatial zones for 18 months if an interaction occurs. Similarly dolphin in interactions in waters of the Coorong region in South Australia are managed in this way. The Coorong is currently closed to gillnet fishing to mitigate dolphin interactions. To reduce targeting, gillnet operators are subject to a rule that constrains their catches of school shark to 20 per cent of their gummy shark catches. The RAG recommended that the same 20 per cent rule be applied to all school shark caught by longline inside 183m. |
Figure 1. Projected future depletion from 2012 stock assessment re-run (pup production divided by pristine pup production) for the school shark stock for the Tier 1 2009 base case assessment model. Projections are shown for 9 future catch scenarios. Catches between 2008 (marked by a vertical line) and 2011 are the actual catches taken by the fishery.

Probability of recommended biological catch (RBC) (or other levels of catch) causing a decline below limit reference under proposed management. Species that follow a HS rule that has been MSE tested will have a “very unlikely” score in this section (i.e. $P<10\%$).

Alternative Catch Scenarios = Projections based on poor recruitment levels (below average recruitment) indicated that catches up to the RBC would deplete the stock rather than allow rebuilding.

RBC: Recommended Biological Catch

Agreed TAC: Agreed TAC

Actual TAC: Actual TAC after overs/unders

% TAC caught: Percentage of TAC caught

Tier 1: Tier 1

MYTAC: Multi-Year TAC
| RAG comments | Standardised CPUE has continued to decline and is at historically low levels, but there are no major changes in other indicators (size composition, age composition, area of the fishery, or depth distribution of the catch). Noting the difference in CPUEs, and a need to capture stock differences between the east and west, SESSF, RAG recommended two separate fleets (east and west).
| Stock indicator trends | The RAG explained that the model assumes average recruitment and if recruitment is different from what is assumed the model may not be able to accurately predict biomass. The RAG warned that a new assessment model may still not be capable of predicting below average recruitment and breakouts may continue.

### Breakout rules for multi-year TAC

- **Fall outside of the 95% confidence interval of the value predicted by the most recent Tier 1 stock assessment:**
- **If discards exceed 20% of the TAC:**
- **If age composition of the silver hoki stock is significantly different from that predicted by the model:**
- **If the proportion of the TAC caught differs by more than 20% from the average over the last three years:**

### Assessment

### Silver hoki fishery performance

- **Fishing season TAC (t)**
  - 2018/19: 604
  - 2017/18: 604
  - 2016/17: 2417
  - 2015/16: 1208

### RAG comments

- **Noting the difference in CPUEs, and a need to capture stock differences between the east and west, SESSF, RAG recommended two separate fleets (east and west).**
considered in the upcoming assessment and that two models be presented to SlopeRAG for consideration i.e. combined fleet and east and west fleet. Recognising that silver warehouse is managed under a single TAC SESSFrag also recommended that SlopeRAG provide a single RBC.

The fit to the last two CPUE data points is poor - the model may be over estimating recruitment and CPUE could be less than predicted leading to a break out again in a relatively short time period.

Additional data will show if the initial signs of a moderate recruitment in 2010 and 2012 are confirmed. Recruitment at the end of the series is very influential and in past assessments has been revised through the inclusion of extra data.

An estimate of the catch for the 2015 calendar year is needed to run the model forward to calculate the 2016 spawning biomass and depletion. Given that recent TACs have been considerably under-caught, the catch in 2015 is assumed to equal that of 2014 (381 t).

The depletion in 2016 under the base-case parameterization is estimated to be 40.5 per cent. An application of the Tier 1 harvest control rule with a target depletion of 48 per cent leads to the 2016 an RBC of 1958t and long term RBC of 2281t.

The RAG has previously noted that there may be a retrospective pattern resulting in upward bias in recent recruitment estimates, and estimates of the spawning biomass kicking up at the end of the projection, despite the fact that the CPUE series continues downwards. The model appears to over-estimate recruitment for the last couple of years, subsequently revising these estimates downwards when additional years of data are added to the assessment.

The RAG was concerned that the 2015 model depletion estimate projections are modelled on the assumption of average recruitment however recruitments have been below average for 9 of the last 10 years, Consequently catching the RBC may take stock to a depletion of just over 30 per cent of unfished biomass by 2019. Under poor recruitment, low catches well below the RBC may protect stock and depletion would be around 40 per cent by 2019.

The RAG briefly considered whether the observed decline in recruitment constituted a downward shift in the productivity of the stock. The RAG decided that it has had no discussions exploring if there are any reasons to substantiate a productivity shift and it would want some additional direct
evidence in addition to the indirect evidence of recent lower estimated recruitment to indicate such a shift. The RAG therefore agreed that reference points should remain unchanged.

The RAG recommended a three year MYTAC, see table above.

| **Key model technical assumptions/parameters** | Stock Synthesis 3 software used for this Tier 1 assessment  
Single sex and single fleet are used in the assessment  
Single stock within the area of the fishery  
Unfished biomass with corresponding age structure is assumed to be at the start of 1979  
M is assumed to be constant with age and time-invariant. Base case value for M is 0.30 yr⁻¹  
Beverton-Holt type recruitment is assumed with a steepness of 0.75  
Growth is assumed to be time invariant  
Recruitment is estimated from 1980 to 2007 |
|---|---|

| **Changes to model structure/assumptions** | The model software was updated from SS-V3.24f to SS-V3.24U.  
The following structural modifications were made to the 2012 model:  
- discarding is now included: discards are estimated within the model and discard length frequencies are included in the model  
- an additional two years of recruitment are estimated as well as the three extra years due to new data (recruitment is now estimated to 2012 c.f. 2007)  
- a single trawl fleet split into east and west  
- length frequency is split into onboard and port components  
- length frequency is now initially weighted by shots/trips  
- Fishery Independent Survey abundance indices included  
- new tuning procedure (based on Francis 2011). |
**Significant changes to data inputs**

3 years of new data were added: catch; CPUE; length and age data to 2014
the ageing error matrix was updated.

### Assessment

**Stock indicator trends**

Unknown due to low effort and catches

**RAG comments**

Smooth oreodory are an aggregating bycatch species taken when fishing for orange roughy and the catch rate may not be a reliable index of abundance.

Smooth oreodory are spatially structured and the model assumes some homogeneity that may not be a reliable estimation of stock distribution.

The RAG agreed that a target depletion of 48 per cent of $B_0$ is needed to be consistent with the SESSF Harvest Strategy Framework.

The RBC is extremely conservative as 90 per cent of the smooth oreodory catch was taken from waters that are now closed.

The previous TAC of 23 t was arbitrary and was set when the deepwater area of the fishery was closed to protect orange roughy. The RAG noted that under the large change limiting rule the maximum the TAC could be is 34.5 t. The RAG agreed that there are no sustainability issues in not applying the large change limiting rule in this instance.

### Key model technical assumptions/parameters

The requirements for DBSRA are:

- catch time series; ideally from the start of the fishery
- a simple model of the dynamics of the fishery.

Plausible values are also required for:

- the natural Mortality Rate: $M$, *model input* 0.05
- the ratio of FMSY to the Natural Mortality: $FMSY/M$, *model input* 0.8
- the most productive stock depletion level: $BMSY/B_0$, *model input* 0.4
- the age at maturity: *model input* 15
- the final depletion level, *model input* 0.48

### Changes to model structure/assumptions

Tier 5 (DBSRA) used to assess this species superseding the
previous Tier 4 assessment.

<table>

Catch trends – Smooth oreody – Cascade
(RBC and total catch are calendar year; TAC and Commonwealth catch are fishing season)
Glossary

**Biological reference points** – quantitative values, often stated in terms of fishing mortality or stock size, that summarise either a desired state for the stock (a target) or a state of the stock that should be avoided (a threshold).

**Biomass** – the total weight of all the fish in a stock or a component of a stock.

**B\textsubscript{LIM}** *(biomass limit reference point)* – the point beyond which the risk to the stock is regarded as unacceptably high.

**B\textsubscript{MEY}** *(biomass at maximum economic yield)* – average biomass corresponding to maximum economic yield.

**B\textsubscript{MSY}** *(biomass at maximum sustainable yield)* – average biomass corresponding to maximum sustainable yield.

**B\textsubscript{TARG}** *(target biomass)* – the desired biomass of the stock.

**B\textsubscript{0}** *(mean equilibrium unfished biomass)* – average biomass level if fishing had not occurred.

**Catch-per-unit effort (CPUE)** – the number or biomass of fish caught as by a unit of fishing effort. Often used as a measure of fish abundance.

**C\textsubscript{TARG}** *(Catch target)* – the target catch level.

**CE\textsubscript{LIM}** *(CPUE limit reference point)* – the point below which CPUE is too low and can indicate stock depletion.

**CE\textsubscript{TARG}** *(CPUE target)* – the target CPUE rate.

**Confidence interval** – also called the confidence bound, a range of values within which the true value most likely lies.

**F** *(fishing mortality)* – the instantaneous rate of fish deaths due to fishing a designated component of the fish stock.

**F\textsubscript{LIM}** *(fishing mortality limit reference point)* – the point above which the removal rate from the stock is too high.

**F\textsubscript{MEY}** *(fishing mortality at maximum economic yield)* – the fishing mortality rate that corresponds to maximum economic yield.

**F\textsubscript{MSY}** *(fishing mortality maximum sustainable yield)* – the fishing mortality rate that achieves maximum sustainable yield.

**F\textsubscript{TARG}** *(fishing mortality target)* – the target fishing mortality target rate.

**Index of abundance** – numerical value used to demonstrate the trend in relative abundance over time.

**Markov Chain Monte Carlo (MCMC)** – an approach to estimate uncertainty in a statistical model by beginning with a final model and shifting its associated parameter values slightly to recalculate the model’s goodness of fit thousands or millions of times.

**Maximum economic yield (MEY)** – the sustainable catch level for a commercial fishery that allows net economic returns to be maximised. For most practical discount rates and fishing costs, MEY implies that the equilibrium stock of fish is larger than that associated with maximum sustainable yield (MSY). In this sense, MEY is more environmentally conservative than MSY and should, in principle, help protect the fishery from unfavourable environmental impacts that could diminish the fish population.
**Maximum sustainable yield (MSY)** – the maximum average annual catch that can be removed from a stock over an indefinite period under prevailing environmental conditions.

**Mortality** – deaths from all causes (usually expressed as a rate or as the proportion of the stock dying each year).

**Overfished** – a fish stock with a biomass below the biomass limit reference point. ‘Not overfished’ implies that the stock is not below the threshold.

**Overfishing, subject to** – a stock that is experiencing too much fishing, and the removal rate from the stock is unsustainable. Also:

- Fishing mortality (F) exceeds the limit reference point (F\textsubscript{LIM}). When stock levels are at or above B\textsubscript{MSY}, F\textsubscript{MSY} will be the default level for F\textsubscript{LIM}.
- Fishing mortality in excess of F\textsubscript{LIM} will not be defined as overfishing if a formal ‘fish down’ or similar strategy is in place for a stock and the stock remains above the target level (B\textsubscript{TARG}).
- When the stock is less than B\textsubscript{MSY} but greater than B\textsubscript{LIM}, F\textsubscript{LIM} will decrease in proportion to the level of biomass relative to B\textsubscript{MSY}.
- At these stock levels, fishing mortality in excess of the target reference point (F\textsubscript{TARG}) but less than F\textsubscript{LIM} may also be defined as overfishing, depending on the harvest strategy in place and/or recent trends in biomass levels.
- Any fishing mortality will be defined as overfishing if the stock level is below B\textsubscript{LIM} unless fishing mortality is below the level that will allow the stock to recover within a period of 10 years plus one mean generation or three times the mean generation time, whichever is less.

**Spawning stock biomass (SB)** – the total weight of all adult (reproductively mature) individuals in a population. Also called spawning biomass.

**SB\textsubscript{MSY}** – Spawning or ‘adult’ equilibrium biomass at maximum sustainable yield.

**Stock assessment** – an evaluation of the past, present and future status of the stock that includes a range of life history characteristics for a species, such as the geographical boundaries of the population and the stock; information on age, growth, natural mortality, sexual maturity and reproduction, feeding habits and habitat preferences; and the fisheries pressures affecting the species.
Guide to completing species assessment forms

This template is prepared to present RAG considerations to inform the AFMA Commission in setting Total Allowable Catches.

Who should complete this form?
RAGs should work together to complete this form as a group. One form should be completed for each species or basket quota species.

How to complete this form
Instructions on what to include in each section are provided in the form itself. Greater clarification has been provided for particular items and can be accessed by following the endnotes provided. RAGs should delete the endnotes in the form prior to submitting it to the Commission.

Briefly summarise the current assumptions regarding stock structure and distribution.

1 Report the most likely stock status against reference points using the base case for the assessment. Trend should be in terms of stock size and fishing intensity.

1 Provide assessments of biomass and fishing mortality using the most recent Fishery Status Reports by the Australian Bureau of Agricultural and Resource Economics and Sciences (ABARES). Complete this section by:

1. using the dropdown lists to select an assessment option
2. insert status with cell colour. Note if species is under a rebuilding strategy.

1 Taken from most recent ABARES report.

1 Potentially useful indicators might include:
   - change in distribution of catch or effort by method
   - non standardised CPUE
   - standardised CPUE
   - size, age composition and recruitment (if available)

Write ‘N/A’ if not required.

1 Use dot points to list the main data inputs for the assessment. In particular, note any significant changes to the inputs. For example, simple updates to catch and effort do not need to be noted.

1 Include main data outputs (eg model calculated discards or productivity) and any data not used.

1 Provide any RAG recommendations on companion or other species that will be affected, or will influence, the ability of a TAC to meet an RBC for this species.

1 This section can only be completed for Tier 1 species as stock projections are not completed for Tier 3 and Tier 4 species. Delete this section if not required.

1 This section should be used to report any available information on likely future trends in biomass or related variables under the current (or a range of) catch levels over a period of approximately 3-5 years following the year of the last assessment.
Research allowance is allocated when there is a specific research proposal available for the RAG to consider. In most cases the Research Allowance will come off the RBC during TAC calculations. Write ‘0’ if a research allowance has not been allocated.

THIS CHART SHOULD ALLOW READERS OF THE SPECIES SUMMARY TO RAPIDLY SEE CATCHES, RBC AND TAC OVER THE RECENT PAST (5-10 YEARS).
